MICROMODEM 100TM

A data communications system for the S-100 computer!

General Description

The MICROMODEM 100 is a complete data communications system for S-100 microcomputers combining on a single board functions which formerly required a modem, an automatic calling unit and serial and parallel interfaces. The result is a sophisticated computer-to-computer or terminal-to-computer modem for use in small computer systems.

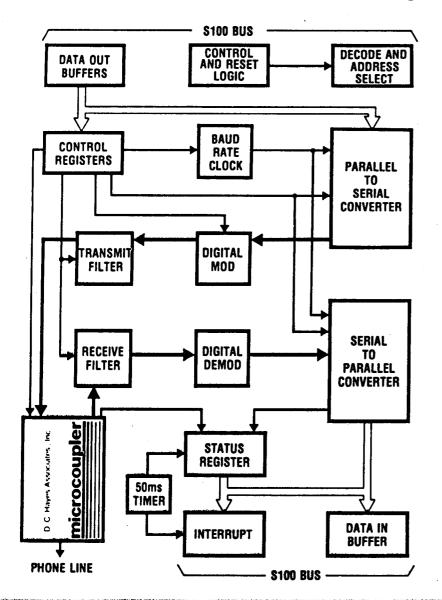

The MICROMODEM 100 provides all the capabilities of a serial interface card and an acoustic coupler, with the addition of programmable automatic dialing and answer.

The MICROMODEM 100 comes with the MICRO-COUPLER™, an exclusive new device that allows you to connect your S-100 computer directly into any modular jack provided by your local telephone company.

Features

- Fully S-100 bus compatible including 16-bit machines and 4 MHz processors.
- Two software selectable baud rates 300 baud and a jumper selectable speed from 45 to 300 baud. (110 standard). Supports originate and answer modes.
- Direct-connect Microcoupler. This FCC-registered device provides direct access into your local telephone system, with none of the losses or distortions associated with acoustic couplers and without a telephone company supplied data access arrangement.
- Auto-Answer/Auto-Call. The MICROMODEM 100 can automatically answer the phone and receive input; it can also dial a number automatically.
- Software compatible with the Ď.C. Hayes Associates
 80-1034 Data Communications Adapter

Micromodem 100™ Functional Block Diagram

Spe	cific	atic	ns

Data Format	Serial, binary, asynchronous 5, 6, 7 or 8 data bits, 1 or 2 stop bits, odd, even, or no parity.
Power consumption	+8 VDC at 250ma, +16 VDC at 25 ma and -16. VDC at 25 ma, typical.
Card Size	5%" x 10" including connector fingers.
Microcoupler™ Size	5½" x 3¼" x 1¾"
Modem Compatibility	Bell System 103-compatible originate or answer mode, dial pulse dialing and auto-answer -50 dBm receive sensitivity -40 or -50 dBm carrier detect level, switch selectable -10 dBm transmit level 45 to 300 baud data rates
FCC Registration	FCC registration No. BI986H-62226-PC-E Ringer equivalence 0.4B Connects with modular jacks RJ11W or RJ11C.

Specifications subject to change without notice

Programming the Micromodem 100™

Registers and Addressing:

The operation of the MICROMODEM 100 is controlled by software. It occupies 4 consecutive I/O port addresses on the S-100 bus. The first port is the data register. All data sent to or received from the phone line goes through this register. Modes of operation are established by setting or resetting bits in 3 control registers. Register #1 controls: parity, word length, number of stop bits and enables interrupts from the 50ms timer. Register #2 controls: baud rate, on/off hook, dialing, transmit carrier, mode, send break, self-test and transmit or receive interrupt enable. Register #3 starts the 50ms timer. The MICRO-MODEM 100 also has a status register which can be read by software. Status bits available are: carrier present, phone ringing, 50ms time-up, character received, transmit buffer empty, parity error, framing error and overrun error.

Automatic Reset and Disconnect:

The MICROMODEM 100 has circuits which, if enabled, can generate an interrupt or reset the CPU if the received carrier is lost. This is useful in systems which are unattended and must cold start if the connection is lost.

Interrupts:

5 interrupts are provided: character received, transmit buffer empty, phone ringing, 50ms time-up and lost carrier. All except lost carrier are individually maskable under program control.

Applications

- Convenient data communications between home and office.
- Automatic data collection from remote terminals.
- Send programs, letters, and other data over the telephone.
- Intelligent terminal.
- · Access to remote data base.
- · Remote software maintenance and customer support.

Ordering Information:

The MICROMODEM 100™ is supplied with:

- Modem interface card
- Microcoupler™
- Connector cables
- Manual including 8080 assembler listing of dumb terminal program

Ask your local computer retail outlet for price and availability information.

1.0 BACKGROUND INFORMATION

The information in this chapter is not essential to using the Micromodem 100. But I believe that you will find it to be helpful and possibly even interesting. Data communications is a fairly complex topic, combining as it does aspects of several related technologies, each of which is a complex and interesting subject in itself.

Data communications is a very confusing subject for most people, including data processing professionals. The subject in inherently complex, and the terminologies are often misleading. This is partly because of the mix of data-processing, electronic, and telephone technologies. Frequently the same words mean different things in the different fields, and when words from the different fields are combined to describe concepts which combine the different fields, they often carry a built-in confusion factor.

I have chosen several of the most important and most confusing topics and have attempted to describe them in plain English. I hope that I have succeeded at least to some extent.

Compatibility With the Bell System 103 Modem 1.1

The Micromodem 100 is designed to be completely compatible with the compountation frequencies and modulation techniques of the Bell System (western The Bell System 103 (and its various Destric) model 103 low-speed modem. equivalents) is by far the most widely-used modem in North America. It is used by virtually all time-sharing systems and dial-up data access systems as their standard mode of access. This popularity is due partly to the relative simplicity of the 103's FSK modulation technique and the reasonable cost of the directory required to implement it and partly due to the fact that there are so many other 103-compatible modems already installed to talk to.

What IS a modem anyway? 1.2

Early in the history of computing (back in the dim distant days of the 1950's), when computers were still huge like dinosaurs and people were just beginning to discover their data processing power, it occurred to someone that you could do a lot of neat things if you had two computers with a wire between them, or a computer and a typewriter if they had a wire connecting them. When they started thinking about wires that ran across the country, they soon began to think about how nice it would be if they could use all the phone wires that were already there.

Unfortunately, as we all know, computers talk digital and telephones are designed to carry the human voice. And the Bell System has lots of smart people who've been working for years and years building black-magic widgets of all kinds that mash and tear up those voice signals in all sorts of inconceivable ways to get them into long-distance wires in the most efficient possible way.

They spent decades researching the human voice so that they knew exactly how much they could mash and distort it and still have it come out recognizable at the other end of the line. If you could send digital data on the phone, who knows what all those widgets might do to it before it got to the other end of the line.

The phone company was worried that digital signals might hurt their various widgets, or might interfere with normal voice signals, so they weren't very encouraging at first.

But the problem did get some study, and some experiments were carried out (mostly by the Bell System). It seems that one thing all the widgets are careful not to disturb is the frequencies of the tones making up a voice. They may distort the amplitude or the phase, but they are careful not to distort frequencies. So a device was built which encoded digital data consisting of ones and zeroes into a signal containing different frequencies for ones and zeroes. This was called a modulator. That was pretty easy. The hard part was building something to un-do the modulating, and turn the tones back into digital ones and zeroes. Suffice it to say that they did figure out a way. They called the un-doer a demodulator.

It turned out that the modulator and the demodulator worked pretty good (better than most people expected). So the phone people put one of each into a box, and started to sell it as data transmission service. Like most engineering types, they weren't at their best with words, so they just took pieces of the words for the parts and stuck them together to make a word for the box. MOdulator + DEModulator = MODEM, thus the modem was born.

Well, a lot of things have happened since those distant days when dinosaurs first spoke to each other over the phone. A lot of research was done on modems. They got faster. And they got bigger and more expensive. In fact, the speed and price have tracked very closely, and there is a common rule of thumb that modems cost about a dollar a baud. But that didn't matter much because the computers they worked with were even bigger and more expensive.

Things happened even faster when the Supreme Court decided to allow competition in the modem business.

At first the phone company insisted that they had a legal monopoly in the modem business because modems were part of the telephone system and they had a legal monopoly to run the phones. Nobody argued. After all, it was pretty obvious that a modem had to be wired up to the phone line, and that certainly made it part of the phones didn't it? But what about the computer wired to the modem? Certainly it wasn't a telephone and the phone company couldn't claim a monopoly on making computers, too. Then along came the acoustic coupler, a modem that wasn't wired up to the phone line. It talked into the phone just like a human, making noises into the mouthpiece, and listening to the noises coming from the earpiece.

The phone company insisted that an acoustic coupler was also a violation of their protected monopoly. The Carterfone company, which built an acoustically-coupled device for use with two-way mobile radios, went to court

after the phone company put them out of business by telling their customers that the acoustic coupler was illegal and threatening to disconnect their telephones if they didn't stop using it.

The court eventually decided in favor of Carterfone (awarding them considerable damages, which helped them to get back in business), and ruled that acoustic couplers were legal. More recent decisions have broadened the rules for interconnect, giving the FCC the power to license devices for use on the telephone network in much the same way that they have long licensed radio transmitters, and limiting the phone company's protected monopoly to running the network which connects the phones together.

Today the dinosaurs, though still very much alive and very much still with us, are giving up center stage to the much smaller, more advanced microcomputers. Small, inexpensive computers need small inexpensive modems, so the old reliable 103-style modem is now even more popular than ever.

1.3 Baud Rates

The term baud often confuses people. And with good reason. It means different things depending on who is using the term, and when. In its narrowest technical definition, a baud is defined as being a measure of the rate at which signals are transmitted through a communications channel, with one baud corresponding to a rate of one signal element per second.

Well, that sounds pretty straightforward, but what's a signal element? With digital data it seems pretty reasonable that a signal element should be the same thing as a bit so that 300 baud would be the same thing as 300 bits per second. Right!? Well, sometimes.

Baud rate is concerned with the stuff (like tones) going down the communications channel (in this case a phone line), and NOT with the stuff (like ones and zeroes) we're turning it into at the other end. In a 103-style modem, each possible change from one frequency to the other is a signal element. Since that is how we code a single bit, one baud equals one bit per second. But the phone line has a very finite rate at which it can carry signal elements. The rate is related to the frequency range the line can accomodate and the modulation technique (as well as the error rate one is willing to tolerate). In general, 1200 baud is about the highest the phones will accomodate with any degree of reliability. So the fastest that a modem can be is 1200 baud (unless you're using some other kind of telephones).

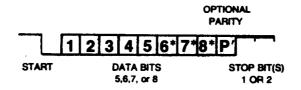

Well where do 4800-baud modems come from then? Well, the answer is that they aren't 4800-baud modems at all. They are 4800 bit-per-second modems. They do it by very cleverly encoding 4 bits of digital data onto a single signal transition (corresponding to a single cycle of a 1200 Hz carrier tone). As you can imagine, it is quite a trick encoding them that way, and even more of one to get them back out at the other end. That's why they're so expensive -- it ain't easy.

But that's not the only confusing part. As data communications users, you

and I don't care how many funny little bauds go down the phone line. In fact we really don't care about the bits even. We are trying to get some bytes moved around, but we'll probably settle for moving ASCII characters.

So how fast can I send characters with a 300 bit-per-second modem? Usually about 30 characters per second, but it can vary. You see, in order to be able to pick the characters out at the receiving end, we have to put on some extra bits to tell where the character begins and ends, etc. So our 7-bit ASCII character is accompanied by one start bit, one stop bit, an optional parity bit for error-checking, and an optional extra stop bit (I don't quite know why, it just slows things down). Thus our ASCII character could get from 2 to 4 extra bits as travelling companions.

The most common usage is one each of start bits, stop bits, and parity bits. This works out nicely because that means 10 bits per character which makes the character rate at 300 baud simple to calculate as 30 characters per second.

Normally, there is no good reason to transmit any slower than you have to (you just get a bigger phone bill), except that it won't work if you send faster than whatever's at the other end can receive it. There are an awful lot of model 33 Teletypes still kicking around. They can send and receive only at 110 baud. Between all those TTY's and the machines built to talk to them, there are still a lot of 103-type modems connected to things that only run at 110 baud.

1.4 Half- and Full- Duplex

This is another very confusing aspect of data communications, and like baud rates is mostly confusing because the terms have been used so loosely and with so little regard for their original very narrow technical meaning.

A communications link which carries data from one point to another in only one direction is said to be a simplex link. Most of the devices (such as radio) which are used for communication are basically simplex devices. To get a two-way communication link, we have to use two simplex links, one going in each direction. This is called a duplex communications link. The telephone is a duplex communications link. The people at both ends of the phone can hear each other. They can even both talk at the same time (except on long-distance sometimes).

MICROMODEM 100 BACKGROUND INFORMATION PAGE 7

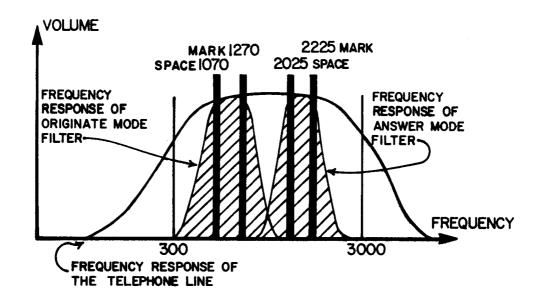

If we have a simplex link which can be turned around, then we can have two-way communications with only one communication path. This is called half-duplex, because it has the effect of a duplex link but with only half as much stuff. CB radio is half-duplex. When one person finishes talking, he has to say "over" or "10-4" or something so the person at he other end knows it's his turn to talk. If they both try to talk at the same time, neither one can hear anything.

To have a full-duplex radio channel, each person would have to have a separate transmitter and receiver, and both people's transmitters would have to run all the time. In order for the two transmitters not to interfere with each other, they would have to use different channels. So full-duplex takes two channels.

Full-duplex communications is easier to use than half-duplex (at least for people), because it is more like normal face-to-face communication. So, even though it takes more stuff to make it work, the phones are built to work full-duplex. The phone in your house has a clever transformer called a hybrid which allows the two signal paths going in opposite directions to share the same pair of wires to the central office. But once it gets to the office, there are more circuits that sort them out, and they are kept that way until they leave another central office on their way to someone's phone.

Long-distance phone circuits always occur in pairs — one circuit going in each direction. On calls that are over a few hundred miles, there is a problem with a full-duplex link. It takes the signals a finite length of time to get from one end to the other. When they arrive, part of the signal goes back into the phone and is sent back where it came from. You get an echo. To fix that, there are gizmos called echo suppressors in the lines. An echo suppressor is a voice—controlled switch that makes the phone line really work half—duplex, but it seems to be full—duplex because the echo suppressors turn around in the space between two syllables.

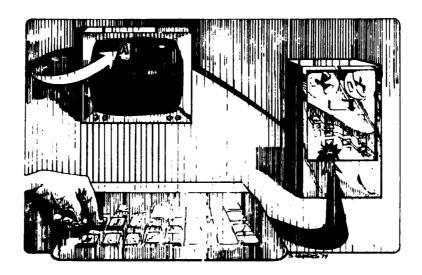

Well, the 103-type modem was designed to be able to take advantage of all those full-duplex communication paths. The designers of the 103 divided the frequency band of the telephone into two narrower bands, and assigned one for sending in one direction and the other for sending in the other. This gave them two channels to work with (like using two CB channels). It worked. Data could go in both directions at the same time. It worked on long distance, and the modems weren't at all bothered by the echos, because the modems were designed to talk on one frequency and listen on the other. They didn't care about the echos because they couldn't hear them.

The only problem was those echo suppressors. They kind of messed things up. Fortunately, someone had already thought of that and put a special disable circuit into the echo suppressors, that made them turn off if they heard a tone in a certain band. One of the tones used by the 103 just happens to correspond to this signal. So as soon as an echo suppressor hears the carrier from a 103 modem, it turns itself off.

Not all modems are full-duplex. In fact, until recently the 103-type was the only full-duplex modem. Most of the faster modems are half-duplex. This makes them more complicated to use beause then the computers at both ends have to say "over" or "10-4" or something and all that. That, of course means a lot of complicated programming.

One nice thing about a full-duplex modem is that you can echo the characters. Virtually all time-sharing and data access systems echo each character back as it is received, and the character is not displayed or printed on the terminal until it has been for a full round trip to the distant computer and back. This gives the person typing a clear indication whether what he typed was received correctly. What he sees is what the computer sees. If a character gets garbled in the phone line, it shows up garbled on his terminal. If it gets lost completely, then nothing shows up on his terminal at all. This technique has a very catchy name, echo-plex.

It is because of this practice that most terminals have a switch marked full— or half—duplex. If the terminal is connected to a half—duplex modem, echo—plex won't work because the computer can't send back the characters it receives. Some systems don't use echo—plex even when they can because it introduces a slight delay which some people find objectionable. In this case, the terminal must display the characters that it sends to the computer. This is all a full—/half—duplex switch does on any terminal. Often the same switch appears on modems (especially acoustic couplers) mostly because it's cheap and looks impressive.

1.5 Ringing and Dialing

Ringing and dialing are two aspects of what the telephone company calls signaling. Signaling is the process by which a connection is established on the switched (dial) telephone network. As is the case with many commonplace things, telephone signalling is much more complicated than it looks.

First let's consider what has to happen when you place a call. The dialog looks something like this:

YOU

I want to make a call.

My girlfriend.

PHONE COMPANY

OK. Who do you want to call?

OK. I'll let her know you want to talk.

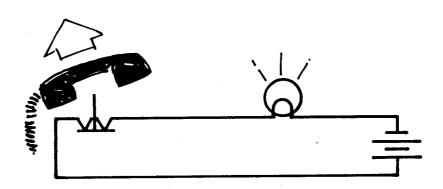

I'm sorry, she's talking to someone else.

Now, that's not such a complicated dialog, but there are a few difficult limitations. For one thing, as we all know, there is seldom a person at the phone company, but some kind of a machine.

Everything that we say to the phone company has to be simple and exact enough for a machine, and everything the phone company says to us has to be simple enough that a machine can make the sounds. Whatever we do, we have to do it with just the two wires that connect us to the central office. And most limiting of all, we have to do it all with technology that was available in 1894, because that's when the dial telephone was invented.

Let's start simple. How does the phone company find out that we've picked up the phone to make a call? Your telephone has a switch on which the receiver normally rests when not in use (the switch hook). When you lift the receiver, this switch establishes a connection between the two wires and allows current to flow from a battery at the central office. This current can be detected at the central office by a light bulb in series with the line, or by a relay.

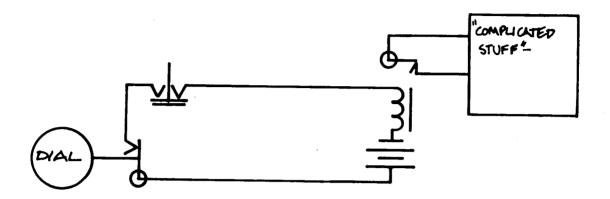

To tell you that it is listening, the central office machinery connects the line to a generator which produces an audible dial tone in your receiver.

To tell the machine who you want to talk to, you dial that person's telephone number. The dial in your phone has a switch that is in series with the switch hook. This switch momentarily breaks the connection between the two wires. When the connection breaks, it causes the relay at the central office to drop out momentarily.

The dial makes a series of these pulses very rapidly. The number of pulses corresponds to the digit you have dialed, from 1 to 10 pulses for the digits 1 to 0. At the central office these pulses are counted by Strowger relays and other more recent devices.

fig 12

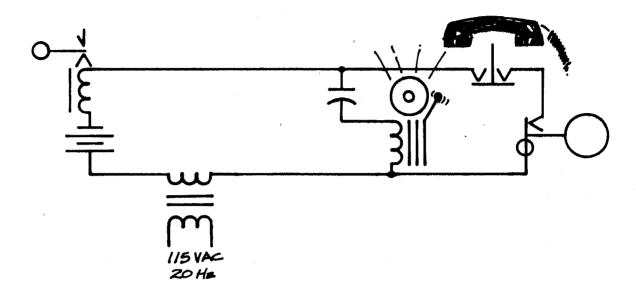

Once you have dialed, a whole bunch of complicated machines that I won't attempt to describe find the pair of wires corresponding to the number you have dialed.

If the line is busy, its phone will be off hook and the relay connected to it will be closed. The machine will then connect your line to another generator which makes a busy signal.

If the line is not busy, then it will connect that line to yet another generator. This one puts out 115 volts AC at 20 Hertz. Your friend's telephone has a bell which is connected to the line via a capacitor. The capacitor prevents the DC current from the battery from flowing through the bell, but allows the AC ring signal to pass through, thus making a loud noise.

When your friend picks up his phone, his switch hook makes connection, drawing current from the battery and activating the relay connected to his line. This causes the ring generator to be disconnected and stops the ringing.

Over the years, many refinements and variations have been added, including tone dialing, in which tones are used instead of the current pulses I have described. Tone dialing may eventually replace pulse dialing, but now and for many years to come, all automatic telephone exchanges accept pulses even if they are designed for tone dialing. Many older exchanges are able to accept only pulse dialing, so for now, pulse dialing is the only universally usable technique.

Well, if you understand everything this far, you can consider yourself to be a minor expert on telephones and data communications. And as the owner of a Micromodem 100, you are now equipped to use that knowledge to advance the state of the art by discovering and developing new applications. Good luck.

2.0 FUNCTIONAL DESCRIPTION

The Micromodem 100 is an S-100 bus compatible device which combines the functions of a serial interface, modem, and automatic dialer on one card. Included with the Micromodem 100 is the Microcoupler. This FCC registered device couples the Micromodem 100 directly to the telephone line without the use of a phone company supplied data access arrangement (DAA). Operation of the Microcoupler is detailed in section 3.

The Micromodem 100 has three main functional blocks. They are the S-100 bus interface, serial interface, and modem. They function together to provide the user with a quality low speed data communication system capable of communicating with other Bell 103 style modems at baud rates from 30 to 300. Operation of the Micromodem 100 is controlled with software. Baud rate selection, dialing, answering calls, originate/answer mode, character formats, etc. are all set by writing data to the Micromodem 100 control registers. See section 5 for details on these registers.

2.1 S-100 INTERFACE

The Micromodem 100 uses the low 8 address lines to decode four I/O addresses from a possible 256. A2 through A7 are used to select the base address while A0 and A1 select 1 of 4 registers for input or output operations. PDBIN is anded with SINP and the output of the base address decoder to provide a read strobe. Data is gated onto the bus during this time. The data source is determined by address line A0. When A0 is low modem received data is read. When A0 is high data from the status register is gated onto the bus. PWR is anded with SOUT and the output of the base address decoder to provide a write strobe. A0 and A1 are used to determine which of the 4 registers will be written into.

		READ ONLY REGISTERS	WRITE ONLY REGISTERS
<u>A0</u>	Al		·
0	0	receive data	transmit data
0	1	status	control req. 1
1	. 0	not used	control reg. 2
1	1	not used	control reg. 3

2.2 TIMER

A 50 millisecond hardware timer is provided so that software timing loops can be eliminated. It consists of a 555 timer chip wired as a non-retriggerable one-shot. Any output to control register 3 will start the timer. Its status may be read in the status register as bit 5. This bit goes to zero when the timer is started and returns to a one after 50 MS have elapsed. This timer bit is also avalable at the interrupt option socket as a low true open collector signal. This interrupt signal can be enabled or disabled under software control by changing bit 5 in control register 1. A 1 enables timer interrupts while a 0 disables them.

2.3 SERIAL INTERFACE

Serial to parallel and parallel to serial conversion is done with the popular AY-5-1013A Universal Asyncronous Receiver Transmitter (UART). The transmit and receive data registers as well as the low 5 bits of control register 1 and the status register are physically located in the UART. This 40 pin chip handles the job of serial-parallel conversion, adding start and stop bits, and generating and checking parity. The serial baud rate is controlled by the baud rate generator.

2.4 BAUD RATE GENERATOR

The baud rate generator provides a square wave clock at 16 times the desired baud rate for the UART. The UART internally divides this clock by 16. The frequency is derived from a 4 MHZ crystal oscillator divided down by U9 and U10. The division ratio of U9 can be varied to provide any baud rate from 30 to 300 baud. 300 baud or a lower user defineable baud rate can be selected under software control by changing bit 0 in control register 2. See section 4.5 for details.

2.5 POWER SUPPLY

The power supply provides 3 regulated voltages for the digital and analog circuits. Two 12 volt zener diodes, CR2 and CR3, supply +12 and -12 volts for the analog circuits. The 7805, a 3 terminal voltage regulator, supplies +5 volts for the digital logic. The Micromodem 100 pulls about 25 MA from the S-100 +16 and -16 volt busses and 250 MA from the 8 volt bus. The Microcoupler is powered from the 5 volt supply and draws about 55 MA.

2.6 MODEM

There are four main parts in the modem section. They are: modulator/demodulator, transmit filter, receive filter, and carrier detect circuit.

The modulator/demodulator is a MC14412 CMOS chip. Serial data from the UART is converted to frequency shift keyed (FSK) data by the modulator. It is a digitally synthesized sine wave. When in ORIGINATE mode a logic 1 from the UART produces a 1270 HZ tone and a logic 0 produces a 1070 HZ tone. When in ANSWER mode a 1 produces a 2225 HZ tone and a 0 produces a 2025 HZ tone.

The demodulator section of the MC14412 takes the received FSK square wave from the limiter and converts it to serial mark/space data for the UART. In ORIGINATE mode a 2225 HZ tone is converted to a logic 1 and a 2025 HZ tone is converted to a logic 0. In ANSWER mode a 1270 HZ tone is converted to a 1 and 1070 HZ is converted to a 0.

In self-test mode the demodulator frequencies are switched to match the modulator. With an external connection, data can be looped back from the transmitter to the receiver for testing purposes.

The transmit filter is a 20 pin hybrid module which contains a 6 pole active band pass filter. Its purpose is to clean up the noise, harmonics, and modulation sidebands present in the synthesized sine wave produced by the modulator before it is sent to the phone line. In ORIGINATE mode it passes frequencies from 950 to 1400 HZ. In ANSWER mode frequencies from 1900 to 2350 are passed.

The receive filter ia a 40 pin hybrid module which contains a 10 pole active band pass filter. Analog signals from the phone line pass through the Microcoupler and are sent to this filter. The desired band of frequencies are amplified by about 20 DB (10 times) and the unwanted signals (noise and transmit carrier) are attenuated by 50 DB (300 times). The receive filter has 2 outputs. a limiter output and an analog output. The analog output is simply the input signal after being filtered and amplified. The limiter output is a 5 volt square wave with the same frequency as the input signal. It is sent to the demodulator where it is converted to serial mark/space data for the UART.

In ANSWER mode the receive filter passes frequencies from $1000~\rm{HZ}$ to $1350~\rm{HZ}$. In ORIGINATE mode frequencies from $1950~\rm{to}~2300~\rm{HZ}$ are passed.

The purpose of the carrier detect circuit is to provide the program with a means of determining the presence or absence of a receive data carrier. This circuit is implemented with a quad OP-AMP, Ul, and half of U2, a dual timer chip. In operation it "listens" to signals passed by the receive filter and sets the carrier detect bit in the status register and lights the LED if those signals are louder than -50 DBM. Noise pulses lasting less than 2 seconds will not activate this circuit because of the action of timer, U2. Only 2 seconds or more of steady tone will register as a valid carrier.

LOST CARRIER DISCONNECT

The lost carrier circuit uses the output of the carrier detect circuit and the on/off hook control to provide an indication that the carrier has been lost for 10 seconds. The main components in the circuit are filp-flop, U6, and timer, U2. The flip-flop "remembers" that a carrier has been present since going off-hook and enables the 10 second timer to start when the carrier is lost. If the carrier returns within 10 seconds the timer is reset, otherwise it times out and activates the lost carrier signal. This signal can be used to reset the CPU if the program crashes and can't poll the carrier detect status bit.

3.0 MICROCOUPLER

The Microcoupler is an FCC registered protective coupler. It's purpose is to protect the computer user and the telephone network from the harmful effects of high voltage spikes and excessive signal levels. It also insures that the telephone billing equipment will properly register and time the calls. The Microcoupler circuity is proprietary and, due to FCC regulations, not user serviceable. For these reasons no schematic is provided. However, to aid the user in trouble shooting his system the following functional description is provided.

The Microcoupler uses only the middle two wires in the four conductor modular telephone cable. These are the red and green wires and are called tip and ring. During the idle condition the telephone system supplies about 50 volts DC between these wires. During ringing 90 volts AC at 20 HZ is superimposed on the 50 volts DC. When a call is in progress the tip to ring voltage will be somewhere between 2 and 16 volts DC at 15 to 120 MA. The DC resistance measured between tip and ring on the Microcoupler is 137 ohms when off-hook (in use) and infinity when on-hook (idle). This measurement is made with the phone line disconnected.

A reed relay controls the on-off hook states and accomplishes the dialing function by pulsing on and off at a 10 HZ rate. The 90 volt AC ringing signal is detected with an optoisolator. The ring detect circuit requires at least 50 volts AC at any frequency between 15 and 70 HZ for 1 second or more.

The Microcoupler has an automatic transmit level control that maintains a constant -10 DBM output into 600 ohms with input levels ranging from -7 to +10 DBM. Inputs below -7 DBM will be passed with a constant 3 DB loss. The automatic level control has no effect on received signals. All transmit signals are sent through a 3 KHZ low pass filter with a 12 DB per octave rolloff.

Signals received from the phone line are passed through a duplexer. The purpose of the duplexer is to seperate the received signals from the transmitted signal. About 10 DB of transmiter rejection is achieved. The duplexer has an output impedance of 600 ohms on both the user and phone line sides. The receive gain is 0 DB when connected to a 600 ohm load or 6 DB when driving a high impedance load such as the Micromodem 100.

The interface between the Micromodem 100 and the Microcoupler is simple and straight-forward. All power, control, and audio signals are sent via a 10 conductor ribbon cable. Signals received from the phone line appear on pin 1. Signals to be transmitted to the phone line are applied to pin 3. Transmitted signals will also appear mixed with the received signals at pin 1 but they will be about 10 DB weaker because of the action of the duplexer. A TTL low level on pin 7 will cause the Microcoupler to go off-hook. Dialing is accomplished by pulsing this line at a 10 HZ rate. Pin 5 is the ring detector output. It is normally high and goes low during the telephone ringing periods. It will drive 1 LS-TTL load. A single 5 volt power source runs all the digital and analog

circuits. Pin 10 is +5 volts, pin 8 is ground. The Microcoupler has a timer which inhibits the transmit and receive audio for 2 seconds after going off-hook. This is for the benefit of the phone company billing equipment.

3.1 MICROCOUPLER INTERFACE CONNECTOR

PIN	NAME	FUNCTION
1	Receive data	Audio signals from the phone line appear on this pin. The output impedance is 600 ohms and the level depends on telco loss30 dbm typical.
2	not used	Key
3	Transmit data	Audio signals to be sent to the phone line are applied to this pin. It has a 47 K ohm input impedance. The maximum input level is +10 DBM. Minimum input level is -7 DBM for a -10 DBM level on the phone line.
4	not used	,
5	Ring detect	Goes low during the telephone ringing signal. It will drive 1 LS-TTL load.
6	not used	
7	Off-hook	A TTL low level on this pin will cause the Microcoupler to go off-hook or answer an incoming call. Audio will be switched through on pins 1 and 3 2 seconds after this line is brought low. It presents 1 TTL load.
8	Ground	Logic and power supply ground
9	not used	
10	+5 volts	+5 volt power supply input. Current required is 55 MA.

INSTALLATION

Identifying the Parts

Your Micromodem 100 is packed with several necessary items. You should take them out of the box and verify that they are all present and in good condition. They are:

- 1) Micromodem 100 printed circuit board.
- 2) Microcoupler for attachment to the telephone line.3) Ribbon cable to connect Micromodem 100 to Microcoupler.
- 4) Modular telephone cable to connect Microcoupler to telephone line.

fig 1

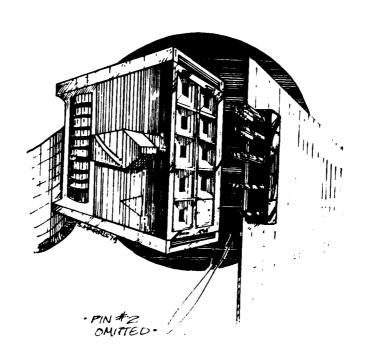

@ 1979 D.C. Hayes Associates, Inc.

4.11 Installing the Micromodem 100 in the Computer

----- MAKE SURE THE COMPUTER IS TURNED OFF! ------

The Micromodem 100 may be installed in any S-100 slot. Before inserting the board in the computer you should set up the various options that you may need for your application. See section 4.2 for details. Once you have set the options and plugged the Micromodem into your computer you can connect the ribbon cable between the Microcoupler and the Micromodem 100. This 10 conductor cable is terminated on each end with identical female connectors. Pin 2 is blocked with a plastic plug. The male plugs on the Micromodem 100 and Microcoupler have pin 2 cut off. This missing pin and plugged hole arrangement form a key which makes it difficult to plug in backwards.

MICROMODEM 100 INSTALLATION PAGE 21

Both ends of the ribbon cable are the same, and are interchangeable. Pick one end and plug it into the Micromodem 100 board. If you have any difficulty plugging it in, try turning it over — it might be backward. When the connector is properly mated, all of the pins will fit easily into their corresponding holes, and the connector body will be flush with the printed circuit board.

Run the ribbon cable out through one of the cable slots in the back wall of the case. You may now replace the cover.

The other end of the ribbon cable connects to the Microcoupler. On one end of the Microcoupler you will see two connectors. In the center of the end wall is a rectangular hole about an inch long. Just peeking through this hole you will see another set of pins just like the ones on the Micromodem 100 board. They are also keyed in the same fashion.

Plug the remaining end of the ribbon cable into this connector. Again, if you have any difficulty, check that it is turned the right way.

You are now ready to connect your computer to the national telephone network.

4.12 CONNECTING TO THE TELEPHONE NETWORK

There are a few details that you need to take care of now before you can legally connect your computer to the telephones. Keep in mind that the Microcoupler is the only part which is FCC registered. The Micromodem 100 and the computer are of no concern to the FCC or the telephone company.

Legal and Technical Details

First you CANNOT legally connect your Microcoupler to either a party line or a pay phone.

Next you need a place to plug it in. If your home or office is already equipped with modular telephone jacks, then you may already have this. You can recognize a modular telephone jack by the small squarish hole (about 3/8") where the modular plug goes in. If you have jacks with four round holes about 3/4" inch apart, then you don't have modular jacks, but an older type of connector. Keep in mind that even if you do have what appears to be a modular jack, it may not be compatable with the Microcoupler. The Microcoupler requires a USOC-RJ11W or USOC-RJ11C modular jack.

4.13 Notifying the telephone company

Before you plug anything into the telephone line you must notify the telephone company. One reason this is necessary that they normally test all their lines on a regular basis. To do this they need to know what's attached to each line, and how many ringers there are on the line. The test measures how much current is drawn on the line. If it draws too much or too little, then they will know that there is something broken or that someone has been tampering with the line. This is how they find illegal extension phones.

You must call the telephone company business office (their telephone number is probably printed on your phone bill) and tell them that you are preparing to install an FCC registered device and wish to notify them. They will need to know what line you are connecting it to (the phone number), the FCC registration number (BI986H-62226-PC-E), the ringer equivalence number (0.4B) and that it needs to be connected to a modular jack USOC-RJ11W or USOC-RJ11C. If you plan to move your computer around, you are allowed to give the phone company a list of phone numbers. Then you won't have to notify them again as long as you move it to one of the lines on your list.

If your phone company has any additional questions about the Microcoupler, ask them to call us in Atlanta.

You are also required to notify the phone company whenever you permanently remove the Microcoupler.

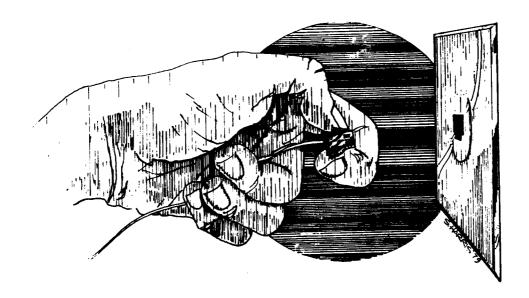

If you experience trouble with your telephone line, you must first disconnect the Microcoupler and make sure that it is not causing the problem. The phone company cannot be responsible for problems caused by your equipment connected to their lines.

In the unlikely event that your Microcoupler causes trouble with your telephone line, you must disconnect it and not use it until it has been repaired. In order to keep FCC approval in force (and thereby be legal), all repairs must be performed by D.C. Hayes Associates, Inc. or our authorized agents. We can repair any problem with your Microcoupler or your Micromodem 100 very promptly. Please see your warranty for full details.

One more legal technicality and you can plug it in. We are obliged to inform you that the telephone company has the right to change their equipment and is under no obligation to make sure that their new equipment is compatible with your Microcoupler. It is very likely that they will change their equipment, but it is extremely unlikely that those changes will render your Micromodem 100 or your Microcoupler unusable. The interface between the Microcoupler and the telephone line is functionally identical to the interface between a standard dial phone and the telephone line. Since the phone companies have millions of dial phones operating today, they are very unlikely to install any new equipment that will render them all obsolete. It would cost too much to replace all those telephones.

Plugging in to the Telephone Line

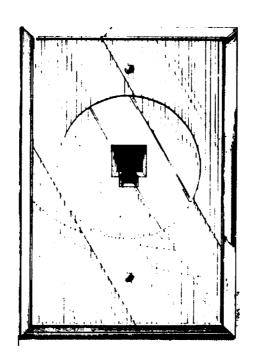

Pick up the modular telephone cable. You will see that there is a small plug on each end. The plug is molded of clear plastic and has 4 gold contacts on one side and a small plastic tab on the other. The plastic tab forms a latch which will hold the plug in the jack. Insert one of the plugs into the modular jack on the Microcoupler. It will only go in one way, and when you put it all the way in, it will make a small snap as the latch takes hold. Pull on the cord. It will not unplug unless you press on the plastic tab.

Now you can plug the other end of the modular cable into the telephone jack on the wall.

This completes the installation of your Micromodem 100.

MICROMODEM 100 INSTALLATION PAGE 24

4.2 USER OPTIONS

All Micromodem 100 boards are shipped from our factory with the following options installed.

PORT ADDRESS	=	80 Hex see section 4.3
WAIT STATES	=	NONE see section 4.4
INTERRUPTS	=	NONE see section 4.7
AUTODISCONNECT	=	OFF see section 4.75
CARRIER DET. LEVEL	=	-50 DBM see section 4.5
BAUD RATES	=	300/110 see section 4.5

Most users will find these options well suited for their application. However, if you want to change any options please read the following text.

4.3 SELECTING AN I/O PORT ADDRESS

The Micromodem 100 occupies 4 consecutive I/O port addresses on the S-100 bus. The first address (base) is set by the first 6 switches in the 8 pole dip switch (S1) on the right side of the board. Switches 1-6 correspond to address bits A7-A2. The desired port address is selected by turning these switches on or off to match the address lines. An ON switch will match a zero and an OFF switch will match a one.

Examples:

Address bits	A7	A 6	A 5	A4	A3	A2
Switch #	1	2	3	4	5	6
port 80 Hex	off	on	on	on	on	on (standard)
port 00	on	on	on	on	on	on
port 04	on	on	on	on	on	off
port OC	on	on	on	on	off	off

The Micromodem 100 is shipped set to port 80 Hex. This is the standard address used by all D.C. Hayes Associates, Inc. software. If this conflicts with another board in your system you will need to set the Micromodem 100 to an unused port address and change the port equates in the software.

4.4 WAIT STATES

The Micromodem 100 will work in most systems at full speed with no wait states. However, some 4 MHZ Z80 or 5 MHZ 8085 based systems may provide a PWR (processor write) pulse which is less than the 300 nanoseconds required by the Micromodem 100. If you install the Micromodem 100 in such a system you should install the wait state jumper. This will insert one CPU wait state during outputs and extend the PWR pulse by one clock period (250 NS at 4 MHZ). No vait states are required for input operations.

Installing a jumper between the pads marked "P3" will activate the wait state circuit.

4.5 BAUD RATES

The baud rate of the Micromodem 100 can be switched under software control between 300 baud and a lower user defined baud rate. Units are shipped with the low baud rate set to 110. Any baud rate from 30.6 to 300 may be selected with an error of less than 2% by installing from 1 to 8 diodes in the baud rate select area. If frequent baud rate changes are required we suggest that you put a 16 pin IC socket in the diode area and wire up several 16 pin headers with diodes for the baud rates you will need.

4.51 BAUD RATE CALCULATION

The 8 diode positions in the baud rate select area form an 8 bit binary number which sets the divide ratio on the baud rate counter. The presence of a diode equals a logic 1 while the absence of a diode equals a logic 0.

Baud rate formulas:

N=Divider ratio B=Baud rate

N=7812.5/B or B=7812.5/N

110 baud example:

N=7812.5/110 = 71.0227

rounded off N=71 decimal or 47 hex or 01000111 binary.

Since one diode is required for each binary 1, four diodes are needed. The actual baud rate obtained will be:

B=7812.5/71 = 110.0352

This is only .032% high.

The diodes are installed as shown in the diagram below. They are 1N4148 or equivilent silicon switching diodes. Note that no baud rate greater than 300 may be selected.

BAUD RATE SELECT O-O (CR14) O-O (CR13) O-O (CR12) O-O (CR11) O-O (CR10) O-O (CR10) O-O (CR9) O-O (CR8)

4.52 VALUE OF N FOR COMMON BAUD RATES

Baud rate	N decimal	N binary		
45.5	172	10101100		
50	156	10011100		
7 5	104	01101000

CR7	0	1
CR8	1	2
CR9	2	4
CR10	3	8
CR11	4	16
CR12	5	32
CR13	6	64
CR14	7	128

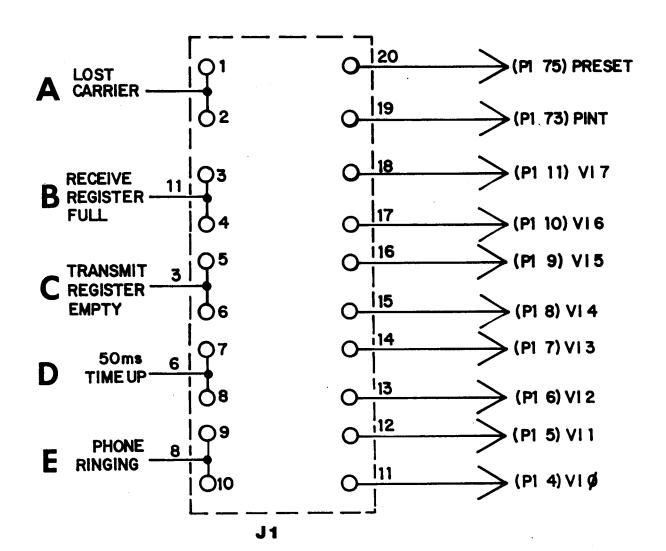

4.6 CARRIER DETECT SENSITIVITY

The carrier detection circuits in the Micromodem 100 will respond to an incoming data carrier as weak as -50 DBM. In most cases this is desirable but sometimes a very noisy line can cause a false indication of carrier. If switch number 7 on dip-switch S1 is turned OFF the carrier detect sensitivity will be reduced to -40 DBM. Since the majority of all data signals are louder than -40 DBM this will have little effect on performance.

If you have problems detecting carrier on weak signals check this switch. Make sure it is in the -50 DBM position (ON).

4.7 INTERRUPTS

The Micromodem 100 provides 5 signals which can be used to generate interrupts. All 5 of these signals and all the S-100 bus interrupt lines are brought out to a 20 pin DIP connector (J1) as illustrated below. All signals are low true and open collector.

MICROMODEM 100 INSTALLATION PAGE 29

Processor reset is also on J1 at pin 20. You may connect the LOST CARRIER or PHONE RINGING signals to this pin if you want the computer to be reset and/or re-boot on one of these conditions. This feature is useful in unattended systems which must recover automatically after a crash.

The following describes the 5 interrupt signals in detail. All signals are active low open collector and may be jumpered to VIO-VI7 or PINT. All except LOST CARRIER are individually maskable. See section 5 on control registers for details.

4.71 PHONE RINGING (E)

This signal goes low for the duration of the 20 HZ telephone ringing signal. Since this signal returns high between rings the program can count them and answer after any number have occurred. It may also be connected to the processor reset line to cause the system to re-boot when the phone rings.

NOTE: This interrupt is enabled only when the Micromodem 100 is in ANSWER mode.

4.72 50 MS TIME-UP (D)

This signal goes low 50 milliseconds after the timer was started. It will remain low until the timer is re—started or the timer interrupt enable bit (D5) in control register 1 is cleared.

4.73 RECEIVE REGISTER FULL (B)

This signal goes low when a character has been received in the data register. It is cleared by reading the data register or by clearing the receive interrupt enable bit in control register 2. (RIE, bit 6)

4.74 TRANSMIT REGISTER EMPTY (C)

This signal goes low when the transmit holding register is empty and ready for another character. It is cleared by writing a byte to the data register or by clearing the transmit interrupt enable bit in control register 2. (TIE, bit 5)

4.75 LOST CARRIER and AUTO-DISCONNECT (A)

This signal goes low 10 seconds after the receive carrier is lost only if the modem is OFFHOOK. If the receive carrier is lost but returns within 10 seconds this circuit will NOT be activated and the 10 second timer will be reset to zero. Note that the time spent dialing and establishing a connection with no

MICROMODEM 100 INSTALLATION PAGE 30

carrier present does not activate this signal because it looks for the presence of a carrier before it arms itself to detect the loss of a carrier.

This signal is provided for emergency re-boot in case the remote user crashes the system then hangs up. It is most useful in single user systems when strapped to processor reset. In normal operation the program should poll the carrier detect bit in the status register and go on hook (hang up) as soon as carrier is lost. If the program can't do this because of a system crash the lost carrier signal will reset the CPU 10 seconds later.

If you only want to reset the Micromodem 100 and hang up without resetting the CPU, the jumper option P4 may be installed.

After connecting LOST CARRIER to an interrupt or reset line you must turn switch 8 on DIP switch S1 to the OFF position to enable this option. This switch is marked ADE (AUTO DISCONNECT ENABLE).

MICROMODEM 100 PROGRAMMING PAGE 31

5.1 PROGRAMMABLE REGISTERS

The Micromodem 100 has two read-only registers and four write-only registers. The I/O port address of these registers is determined by switches 1 thru 6 on DIP switch S1. See section 4.3 for details on selecting a base address. The standard base I/O port address is 80 Hex.

PORT	F	READ-ONLY REGISTERS	WRITE-ONLY REGISTERS
base+0	(80)	receive data	transmit data
base+1	(81)	status	control reg. 1
base+2	(82)	not used	control reg. 2
base+3	(83)	not used	control req. 3

5.2 TRANSMIT DATA REGISTER

ADDRESS = base+0 (write only)

Data written into this register is converted to serial FSK data and transmitted over the phone line. When 5, 6, or 7 bit characters are used the remaining most significant bits in the byte are not transmitted and their value has no effect on the transmitted data. Data should be written into this register only when the TRANSMITTER REGISTER EMPTY (TRE) bit in the status register is a one (1). This bit should be tested before each output to the transmit data register.

The transmitter is double buffered. It actually has a holding register, which the program writes characters to, and a transmit register which does the parallel to serial conversion. When a character is written into the holding register the transmit register is automatically tested to see if it is empty. If it is found to be empty, the character in the holding register is loaded into transmit register and converted to serial data. When this happens the TRE bit in the status register is set to a 1 to indicate that the holding register is ready for another character. If the transmit register had been busy sending the previous character the TRE status bit would have remained low until the holding register could transfer its contents to the transmit register. All of this may seem complex but it is all handled automatically by the UART chip so the programmer doesn't have to worry about it.

5.3 RECEIVE DATA REGISTER

ADDRESS = base+0 (read-only)

This register will contain the received data from the phone line. It should be read only when the RECEIVE REGISTER FULL (RRF) bit in the status register is a one (1). Reading this register resets the RRF bit.

5.4 STATUS REGISTER

ADDRESS = base+1 (read-only)

bit

function

7	6	5	4	3	2	1	0
-RI	CD	TMR	OE	FE	PE	TRE	RRF

BIT 0 = RRF (RECEIVE REGISTER FULL)

RRF = 0

no data

RRF = 1

data byte received in data register

This bit indicates that a character has been received in the DATA REGISTER. Reading the data register will reset this bit.

BIT 1 = TRE (TRANSMIT REGISTER EMPTY)

TRE = 0

transmitter busy

TRE = 1

transmitter ready for next character

This bit indicates the status of the transmit register. When it is a one (1) the transmit register is ready to accept a character.

BIT 2 = PE (PARITY ERROR)

PE = 0

no parity error

PE = 1

parity error on last character received

This bit, when set, indicates that a parity error was detected in the current character in the receive data register. This bit will remain set until an error free character is received. If the "no parity" mode is selected this bit will always be zero.

BIT 3 = FE (FRAMING ERROR)

FE = 0

no framing error

FE = 1

framing error on last character received

This bit, when set, indicates that the UART receiver failed to detect a stop bit at the proper time and the contents of the receive register are probably invalid. This bit is reset when a character is properly received.

BIT 4 = OE (OVERRUN ERROR)

OE = 0 no overrun error

OE = 1 lost 1 or more characters

This bit, when set, indicates that the data register was not read before the next character was received. This can only be caused by software bugs.

BIT 5 = TMR (TIMER STATUS)

TMR = 0 50 MS period in progress

TMR = 1 50 MS or more have elapsed

This bit indicates the status of the 50 MS timer. It goes to zero when the timer is started and stays zero for 50 milliseconds.

BIT 6 = CD (CARRIER DETECT)

CD = 0 no data carrier present

CD = 1 data carrier present

This bit indicates the status of the received carrier. This bit should be checked frequently during communications to make sure a connection still exist. This bit affects the LOST CARRIER circuits. See section 4.75 for details of automatic disconnect on loss of carrier.

BIT 7 = RI (RING INDICATOR [low true])

RI = 0 the phone is ringing RI = 1 the phone is NOT ringing

When this bit is zero the phone line is ringing. It goes to a one (1) between rings so they may be counted.

5.5 CONTROL REGISTER 1

ADDRESS = base+1 (write-only)

bit 6 5 4 3 2 1 0 function X ΡI SBS LS2 LS1 X TMIE EPE

BIT 0 = EPE (EVEN PARITY ENABLE)

EPE = 0 odd parity EPE = 1 even parity

This bit selects the type of parity to be generated or checked.

BIT 1 and BIT 2 = LS1 and LS2 (WORD LENGTH SELECT)

LS2	LSI			
0	0	5	data	bits
0	1	6	data	bits
1	0	7	data	bits
1	1	8	data	bits

These two bits set the length of the data word to be transmitted and received.

BIT 3 = SBS (STOP BITS SELECT)

SBS = 0 1 stop bit

SBS = 1 2 stop bits for 6, 7, or 8 data bits

1.5 stop bits for 5 data bits

This bit sets the number of stop bits to be transmitted and received.

BIT 4 = PI (PARITY INHIBIT)

PI = 0 parity is generated and checked

PI = 1 no parity

This bit determines if parity is used during transmitting and receiving. Bit 0 sets the type of parity (even or odd).

BIT 5 = TMIE (TIMER INTERRUPTS ENABLE)

TMIE = 0

interrupts from 50 MS timer disabled

TMIE = 1

enable timer interrupts

When this bit is set to a 1 the timer will generate an interrupt when it times out if the jumper has been installed on J1. See section 4.7 for more information about interrupts.

BITS 6 AND 7 ARE NOT USED

5.6 CONTROL REGISTER 2

ADDRESS = base+2 (write only)

bit

function

7	6	5	4	3	2	1	0
ОН	RIE	TIE	ST	BRK	MS/RID	TXE	BRS

BIT 0 = BRS (BAUD RATE SELECT)

BRS = 0

low baud rate (user selectable, 110 std.)

BRS = 1

300 baud

This bit selects 1 of 2 baud rates for transmitting and receiving. See section 4.5 for information on user defined baud rates.

BIT 1 = TXE (TRANSMITER ENABLE)

TXE = 0

modem transmit carrier OFF

TXE = 1

modem transmit carrier ON

This bit turns the modem transmitter on and off. It should always be turned off prior to changing the originate/answer MODE select bit.

BIT 2 = MS/RID (MODE SELECT/RING INTERUPT DISABLE)

MS/RID = 0

answer mode, ring interrupts enabled

MS/RID = 1

originate mode, ring interrupts disabled

This is a dual purpose bit. Its primary function to switch the modem between the answer and originate modes. It also controls interrupts from the ring detector. It must be in ANSWER mode if interrupts from the ring detector are wanted. Of course the ring interrupt jumper on Jl must be installed. See section 4.5 for details. Also note that the ring indicator bit in status register is NOT affected by the state of this bit.

The TXE bit must be ZERO before changing the state of the MS/RID bit. The MC14412 modem chip will sometimes lock up in a strange mode if this is not done.

BIT 3 = BRK (BREAK)

BRK = 0 normal operation

BRK = 1 exchange mark and space frequencys

this effectivly sends a break (constant space)

This bit is normally used to send a break signal (required by some time-sharing services). A BREAK is a steady SPACE tone for at least 3 character times. To send a break, the program should wait 1 character time after TRE goes true to allow the last character to be sent by the UART, then set the BREAK bit for 3 character times. This bit should then be reset to return to normal operation.

You can also detect reception of a BREAK. There is no bit in the status register that will give a direct indication but it can be done indirectly. A BREAK will always cause a FRAMING ERROR and the data register will be zero. The program can check for these conditions and assume a BREAK has been received.

BIT 4 = ST (SELF-TEST)

ST = 0 normal mode ST = 1 self-test mode

When this bit is set to a 1 the modem receiver switches modes so that it "listens" to the transmitter. Data sent by the transmitter can then be received by the receiver for local testing. The Microcoupler should be disconnected when using the self-test mode.

BIT 5 = TIE (TRANSMIT INTERRUPTS ENABLE)

TIE = 0 transmit interrupts disabled TIE = 1 transmit interrupts enabled

This bit controls interrupts from the transmitter. When it is a one an interrupt will be sent to the CPU each time the transmit data register is empty. The interrupt jumper at Jl must be installed. See section 4.7 for details.

MICROMODEM 100 PROGRAMMING PAGE 38

BIT 6 = RIE (RECEIVE INTERRUPTS ENABLE)

RIE = 0 receiver interrupts disabled RIE = 1 receiver interrupts enabled

This bit controls interrupts from the receiver. When it is a lan interrupt will be sent to the CPU each time a character is received in the data register. The jumper on J1 must be installed. See section 4.7 for details.

BIT 7 = OH (OFF-HOOK)

OH = 0 on-hook (idle)

OH = 1 off-hook (pick up phone)

This bit controls the telephone switch-hook in the Microcoupler. It is set to a one to answer incoming calls and with appropriate software can perform the dialing function.

5.7 CONTROL REGISTER 3

ADDRESS = base+3 (write-only)

This register is used to start the 50 MS timer. It has no data bits. Simply writing anything to this register will start the timer. When started, bit 5 in the status register will go to a zero for 50 MS. Timer can't be triggered again until the end of the 50 MS period.

TERMINAL PROGRAM

The terminal program is written in 8080 assembly language. It will run on any 8080, 8085, or Z80 machine that uses the CP/M disk operating system. It can be modified for other operating systems by changing those portions of the program which are CP/M dependent. This requires a good understanding of 8080 assembly language and the system it will be run with.

The terminal program is intended to be an example of programming techniques for the Micromodem 100 and not the "last word" in data communication programs. It is split into four sections; Terminal control, Disk I/O, Console I/O, and Modem I/O. You are invited to use the modem I/O section to build your own programs around. The console and disk I/O sections are CP/M dependent and should be changed if you intend to use it with a NON-CP/M system. The terminal control section decodes and executes all user commands. It can be expanded by adding more commands to the table "TABLE".

As is, the terminal program will allow its user to call time sharing computers and transfer data or programs to or from disk. It can communicate with a copy of itself in another S-100 machine to send data back and forth. Also, it has been used to transfer messages in and out of computerized bulletin board systems (CBBS).

LIST OF COMMANDS

Command	description
A	Wait for phone to ring, then answer call
AA	Answer call immediately
AO	Answer call immediately but in ORIGINATE mode
B1	Set baud rate to 110
B3	Set baud rate to 300
C0	Clear capture buffer, disable capture
C1	Start capturing received data in buffer
C2	Stop capturing (Cl will start again at this point)
D5551212 D	Dial phone number 555-1212, then wait for carrier Redial last number dialed
F	Set for FULL DUPLEX (no local echo)

D	Δ.	F.	Δ	3

A	PP	CA.	in.	rv	A
А	PP	r.n	11)	I X	А

X

TERMINAL PROGRAM

•	
G	Goodbye, hang up phone
н	Set for HALF DUPLEX (local echo)
J4F13	Jump to address, in this case 4F13. This is useful for getting out of the terminal program and into a monitor or debugger. The terminal program can be re-entered at HEX 100.
L5 L6 L7 L8	Set data word length to 5 bits 6 bits 7 bits 8 bits
PE PO PN	Set for EVEN parity ODD parity NO parity
R TEST.MSG	Read CP/M file "TEST.MSG" from disk and transmit it.
S1 S2	Set STOP BITS = 1 STOP BITS = 2
т	Type capture buffer to console
T5A	Type capture buffer to console starting at the HEX 5A'th character. NOTE: S starts and stops the listing Carriage return aborts this function.
w test.msg	Write the contents of the capture buffer to disk in a file named "TEST.MSG".

Exit to CP/M (does warm boot)

?1 Debug mode ON. All incomming data will be displayed in HEX with 16 bytes per line. Please note that your console device must be at least 4 times as fast as the modem baud rate

?0 Debug mode OFF.

Multiple commands may be typed on a line if they are seperated by commas or spaces.

Example: COMMAND:L7,PE,S1,F,D3944220 <CR>

In this example the word length is set to 7 bits, even parity is selected, 1 stop bit, full duplex, then the phone number 394-4220 is dialed. The line is ended with a carriage return. Once the options are set they remain in force until changed.

Some telephone exchanges require you to dial a digit then wait for a second dial tone before dialing the remaining digits. This can be done by putting a "*" in the phone number where pauses are required. The dialing program will wait 2 seconds when it encounters the "*".

example: COMMAND: D 9*3944220 <CR>

When a call is in progress you can return to the command mode without interrupting the call by typing a control A. The program will prompt with "COMMAND:". You can then enter a line of commands and hit carriage return. The commands will be executed and the program will return to communication mode. The control A and the command line will NOT be transmitted to the line. Also, all data from the line will not be received during this time.

Some time sharing systems require a BREAK to stop print-out. Type control W to send a break.

If control A or W conflict with control characters you need to transmit you can change the program to accept any control codes you want. Just change the two CPI statments in the "CSEND" subroutine and re-assemble the program.

You can exit to CP/M during a call without hanging up. Type control A then the command "X". It will then ask "do you want to hang up first". Type N and CP/M will re-boot and the connection will still exist. If you don't load any other programs which overwrite the Terminal Program RAM area at 1000 HEX you can re-enter by loading and executing the Terminal Program .COM file as if it were a cold start. When the program starts running at 100 hex it will check for a receive carrier. If none is present it will go through the cold start initialization code. If it detects a carrier it will compute the checksum of the scratch pad ram area. If the ram has not been changed it will go directly to the communication loop and type "CONNECTION ESTABLISHED". If the ram has been altered it will print "REENTRY IMPOSSIBLE", reset the modem, and cold start.

This program is available on a CP/M format 8 inch single density floppy disk from D.C. Hayes Associates, Inc. for \$25.00. Georgia residents please add 4% sales tax.

TITLE 'REMOTE CONSOLE FOR CP/M AND THE MICROMODEM 100'

:WRITTEN BY DALE HEATHERINGTON

; COPYRIGHT 1979, D.C. HAYES ASSOCIATES, INC.

;THIS PROGRAM ALLOWS THE USER TO IMPLEMENT THE ;MICROMODEM 100 AS AN ADDITIONAL CONSOLE FOR CP/M.
;IT WILL ONLY WORK WITH VERSION 1.4 BECAUSE IT ;DEPENDS ON THE SPECIAL FEATURE WHICH CHECKS THE ;CONSOLE BUFFER FOR A COMMAND JUST AFTER WARM BOOT.
;THE NAME OF THIS PROGRAM MUST BE IN THIS BUFFER SO ;IT WILL EXECUTE EACH TIME CP/M BOOTS UP. THE "INSTALL" ;PROGRAM TAKES CARE OF PUTTING THE NAME IN THE BUFFER.

----- OPERATION -----

;WHEN CP/M BOOTS IT LOOKS IN ITS CONSOLE BUFFER. IT ;FINDS "REMOTE" AND LOADS IT. THIS PROGRAM THEN USES ;THE ADDRESS AT LOCATION 6 TO FIND OUT WHERE THE BOTTOM ;OF THE CCP (CONSOLE COMMAND PROCESSOR) IS. IT THEN ;RELOCATES ITSELF 512 BYTES BELOW THE CCP AND CHANGES ;THE ADDRESS AT LOCATION 6 TO INDICATE A NEW TOP OF USER ;MEMORY. IT THEN GETS THE FIRST 5 JUMPS FROM THE CBIOS ;JUMP TABLE AND MOVES THEM INTO ITS OWN MEMORY SPACE. ;THESE JUMPS ARE ALL THE CONSOLE FUNCTIONS. IT THEN ;PUTS JUMPS TO ITS OWN MICROMODEM 100 CONSOLE ROUTINES ;IN THE CBIOS JUMP TABLE. IT THEN RETURNS TO CP/M ;WHICH PUTS UP THE PROMPT A>

; THE NEW CONSOLE STATUS ROUTINE CHECKS FOR PHONE RINGING ; AND CARRIER DETECT AS WELL AS MODEM CHARACTER RECEIVED. ; IT THEN USES THE OLD CBIOS CONSOLE STATUS VECTOR TO CONTINUE ; ON TO THE CBIOS ROUTINE.

;THE USER OF CP/M AT THE LOCAL CONSOLE WILL NOTICE NO;DIFFERENCE IN THE OPERATION OF CP/M EXCEPT THAT LESS;MEMORY WILL BE AVALABLE FOR TRANSIENT PROGRAMS. ALSO;"STAT" WILL ALWAYS RETURN OK BYTES LEFT FOR SOME;UNKNOWN REASON. WHEN THE PHONE RINGS IT WILL ANSWER;AND PUT A CARRIER ON THE LINE. THEN IT WAITS 15 SECONDS;FOR THE CALLER TO SEND A CARRIER. IT HANGS UP IF NO;CARRIER IS DETECTED. WHEN IT DETECTS A CARRIER IT;REBOOTS CP/M SO THE CALLER WILL GET THE PROMPT A>.

; IF YOU WANT TO MAKE MODIFICATIONS TO THIS PROGRAM ; MAKE SURE YOU MARK ALL ADDRESS WHICH WILL BE RE-LOCATED ; WITH SOME LABEL AND PUT THAT LABEL IN THE RELOCATION TABLE. ; I USED "RL" FOLLOWED BY A DIGIT FOR LABELS WHOSE SOLE ; PURPOSE WAS TO MARK RELOCATED ADDRESSES.

TITLE 'INSTALL OR REMOVE REMOTE CONSOLE'

```
;THIS PROGRAM WILL INSTALL OR REMOVE ;REMOTE CONSOLE IN 1.4 CP/M.;NAME: INSTALL.ASM
```

;WRITTEN BY DALE HEATHERINGTON

#001

; COPYRIGHT 1979, D.C. HAYES ASSOCIATES, INC.

;THIS PROGRAM ONLY WORKS WITH VERSION 1.4 CP/M.
;IT LOADS THE FIRST 128 BYTES OF THE CP/M CCP MODULE
;INTO RAM AT 80 HEX. THIS IS ASSUMED TO BE ON TRACK ZERO,
;SECTOR 2. IF THE USER TYPES "I" TO INSTALL REMOTE CONSOLE
;THE PROGRAM WILL INSERT "REMOTE" INTO THE CCP CONSOLE BUFFER
;ALONG WITH IT LENGTH, 6. IT THEN WRITES THIS MODIFIED SECTOR
;OF THE CCP BACK TO THE DISK. "REMOVE" WORKS THE SAME
;EXCEPT THAT IT SETS THE LENGTH TO 0 AND WRITES 6 SPACES TO
;THE CONSOLE BUFFER.
; WHEN CP/M WARM BOOTS IT CHECKS THE CONSOLE BUFFER TO SEE
;IF IT HAS ANY THING IN IT. IF IT DOES CP/M READS IT AND

; WHEN CP/M WARM BOOTS IT CHECKS THE CONSOLE BUFFER TO SEE; IF IT HAS ANY THING IN IT. IF IT DOES CP/M READS IT AND; PERFORMS THE FUNCTION. IN THIS CASE IT WILL LOAD AND EXECUTE; THE FILE "REMOTE.COM", THE REMOTE CONSOLE PROGRAM.
