

```

; This is an 8086/80386 monitor for the 8088, 8086, 80286 or 80386 S100Computers.com boards
; It is a modification of the earlier 8086 monitor used with the S100Computers 8086 Board, IDE Board,
; ZFDC board, MSDOS Support (PIC & RTC) Board and other hardware as well.
;
;   John Monahan, San Ramon, CA   Started, December 2012. (monahan@vitasoft.org)
;
; History
;
; V0.1   12/19/2012   ;Original version V8.8 8086 Monitor modified for 80386
; V0.2   12/24/2012   ;Started adding protected mode menu options
; V0.3   12/28/2012   ;Added ability to switch back to 80386 real mode from protected mode
; V0.4   12/31/2012   ;Added PM A,M,V,R menu commands
; V0.5   1/1/2013     ;Addeed Q, & F commands
; V0.6   1/2/2013     ;Added J,G,H commands
; V0.7   1/13/2013    ;Modified real mode interreupt testing commands. Orgin moved to F000:0H (from F000:8000H)
; V0.8   1/16/2013    ;RM mode soft interrupts working with relevent vector # display
; V0.9   1/17/2013    ;PM Interrupts tests added
; V0.91  1/19/2013    ;Set Date error with "E" comand corrected. Also RM display all registes with "R" command
; V1.0   1/26/2013    ;Change default RAM loacations for GDT IDT etc. Set so it can be easily loaded with PCLOAD.COM
; V1.1   1/30/2013    ;Add Interrupt 0-3ffH in RAM. Correct PM Debug Interrupts
; V1.2   2/3/2013     ;Implemented Hardware breakpoints (DR0-3)
; V1.3   2/5/2013     ;Implemented XModem file transferrs (RM & PM) "W" menu option
; V1.31  2/8/2013     ;Fixed 80386 JZ,JNZ jumps so they are within range for 8086
; V1.32  2/10/2013    ;Minor cleanups including PATCH:
; V1.33  2/18/2013    ;Corrected Z menu option display
; V1.34  2/21/2013    ;Hardware test/read RAM above 16 MG ("E" command)
; V1.35  2/22/2013    ;Fixed PM Mem move error
; V1.36  4/17/2013    ;Fixed memory map displaying RAM and RAM testing above 16MG for areas with no RAM chips
; V1.4   7/29/2013    ;European Cruise updates/cleanup
; V1.41  10/23/2013   ;Correct duplicate "ZFDC not present" message upon initalization and Memory Compare display errors
; V1.42  12/18/2013   ;Added PM "Y" menu option to test running test code at any location including a location above 16MB
; V1.43  3/16/2014    ;Added PM "J" command to test RAM 1-16MB extensively
; V1.44  3/20/2014    ;Changed "Z" to allow return Z80 master using V2-SMB ports
; V1.45  5/25/2014    ;Generalize memory testing (J command anywhere in RAM), corrected XMODEM
; V1.46  5/27/2014    ;Redo Executing test code in RAM > 16 MB ("Y" command)
; V1.47  7/20/2014    ;Corrected IDE Menu X & Y commands display in menu
; V1.48  8/3/2014     ;Major changes/improvement to PM RAM testing routine
; V1.49  8/23/2014    ;Added loop RAM RD/WR test for hardware signal analysis with logic probes etc.
;
;
; To Do:-
; Caps Lock key is showing as ^ on for MS-DOS command line on Propeller & LAVA video boards (Fix on propeller board)
;
; Notes...
; The monitor should work fine with an 8086/80286 CPU for all menu options except the 32 bit protected mode menu section.
; However I have not checked this point out thoroughly. For these chips you should really use the 8086 monitor.
; Also it will not fit in the S100Computres/N8VEM boards 8086/8088's 32K address space with 28C256 EEPROMS.
; You will need to use 27C256 UV-EPROMS.

```

```

;
; This fairly extensive 80386 monitor consists of 4 main sections. Section 4 assumes an 80386
;
; Section 1. This is a classical monitor. Display, change RAM/ports etc.
; Section 2. This is a self-contained set of routines run diagnostic tests on the S100Computers/N8VEM IDE board.
; Section 3. This fairly complex section. It emulates most of the IBM-PC ROM BIOS interrupts (hard & soft) such that MS-DOS
; (V4.01)/FreeDOS can be run on the system - without any DOS modifications.
; Section 4. This is a section written in 32 bit code. It requires an 80386 to run in Protected mode and
; has 0-4GB RAM addressing capability as well as interrupt processing (IDT table).
; The code runs at privilege level 0 with no assigned tasks.
;
; In general the 32 bit specific routines for the 80386 all start with "P_" (e.g. P_EAX_HEXOUT). These must be used when
; the CPU is in protected mode. The most common error is calling a 16 bit routine instead of the equivalent 32 bit one
; when the CPU is in protected mode. This will usually result in a FAULT interrupt.
;
; In the final EEPROM it will be placed at F0000H, the stack is at DFFFCH, and the IDE Board RAM buffers/BP at DE000H.
; For debugging/testing this monitor will reside in RAM at E0000H (the stack is still at DFFFCH & IDE RAM buffer/BP at DE000H).
; For mode (PM), the GDT is at D0000H and the IDT is at D0100-D08FFH. I place the stack an BP here so that test versions of the
; monitor can be uploaded to E0000H by the monitor "W" command without overwriting the stack.
;
; This monitor needs a valid stack in RAM. It first checks if there is valid RAM in high memory below the ROM
; (The EEROM is usually at F0000H). If so it will set the SS to D000H and the SP to FFFCH. This puts it out of the way
; of everything in low RAM. If it does not detect RAM there, it will search for a valid segment from there in RAM downwards and
; put the stack at the first "top of RAM" available.
;
; That is the only RAM the main PM monitor needs. However the IDE drive diagnostic routines require much more (sector buffers etc.)
; I have set the BP to E000H. We use SS:BP throughout to access that RAM for the IDE Board diagnostic section.
;
; Remember also, that RAM 0-3FFH can be initilized to trap all interrupts in RM. If you want this, activate the
; SETUP_INT_TABLE routine at the start of this code. Otherwise they are not used/activated unless you use the "L" and "I" commands.
; In PM the ints are always active and will trap most errors and can be used for single stepping deugging etc.
;
; Most monitor commands are modeled after the old TDL/Zapple/Z80 commands. Because we are now dealing with potentially up
; to 4GB of RAM for many commands, the start, end RAM locations etc. can take up to 8 digits!
; In Protected mode/80386, the actual span/range for any command is NOT limited to 64K as for the 8086 monitor.
; In real mode however the limit is still 64K.
;
; The following example fills RAM with 76H from 1A000H to 21234H.
; F100000,200000,7676
; Of course for the lowest 64K of RAM the "normal" 4,3,2 or 1 byte formats can be used
; F123,456,76
;
; In general hitting the ESC key will abort any long display/command function.
; In all cases, to accept data, finish the entry with a CR.
; So if the display says "xxxxH" you enter up to 4 hex digits than a CR (No "H" is required).
;
; To test/load the monitor...
;
; There are a number of ways to test/run this monitor. Until you actually have this monitor in EEPROM, you

```

```

; can assemble it with a origin in low RAM (say MonitorORG = 4000H). Until you have a working version you should
; have your 80386 (or 8086) after reset jump to the debugging monitor in low RAM. Use PLOAD (see the S100Computersw.com
; web site or see below, how to do this).
;
; The debugging version can be anywhere in RAM but the easiest location is something like 4000H. It needs to be
; well above 100H, because the Stack & Data areas are BELOW the ORG or the final EPROM code. These may have to be
; assigned different locations in the equates below if you don't have RAM at 0D0000H.
;
; Assemble to a binary file with the excellent/free MSDOS/FreeDOS, NASM.EXE Assembler
; NASM -f bin 8086.A86 -o 8086.bin -l 8086.lst
;
; This will make a 8 bit format .bin file
;
; Move it across to your CPM80 disk file system (Telnet/Modem/serial connection), whatever. I use my program PLOAD.COM.
; This is a small CPM program that takes ModemZ file format data from a PC (the above .bin file) via a serial port and places it in the
; S100 bus RAM anywhere from 1000H up to 1MG. For locations greater than 64K it assumes a S100Computers Z80 CPU S100 board
; This board has a 16K window capability to access RAM > 64K. PLOAD.COM can be downloaded from the S100Computers.com web site.
;
; After switching to your 8086/80386 Board (IN port EDH), the CPU starting up initially from an reset will begin at
; @FFFF0H (F000:FFF0H) in RAM:. There you should have code to jump to the start of the monitor.
; If for example it resides in RAM at 4000H you should have the bytes:- EA 00 40 00 00.
;
; BTW, in the monitor code here, before such a jump, there is a small piece of code that reads bits 7&6 of the IOPORT
; and IF 0's just outputs a characater on the Console. This is a usefull hardware test
; when you are first building a board or testing hardware. See the end of the code here for more info. However you dont
; need this code if you are doing things by hand i.e. jumping to the the start of the monitor in low RAM.
; Finally (if installed in hardware), some diagnostic LED's can be turned on as the monitor loads. Again not necessary, but usefull.
;
; Once you have the Monitor itself working its own "W" command will read a modem serial port and upload a test version of the monitor
; into RAM (currently) configured to start at whatever 4K boundry you designate (usually E0000H). You don't need CPM or the Z80 card.
; When done, use the Master Z80 monitor "W" command to activate the 80386 board (not the "O" cmmand) if your code is in RAM.
;
; Note in the code there are a few FAR JMP's in the code, and in PM there are critical tables that must be positioned
; carefully. Be sure the equates below have the correct values.
;
; That said the whole monitor fits easily within one 8086 style segment. So for example it will run unchanged in RM at say:
; F000:0000H, E000:0000H, 1000:0000H.... etc. just make sure you have RAM below it configured for a stack.
; Remember PM mode requires careful positioning of the GDP and IDE tables.
;
; As soon as you get things going, burn a EEPROM version that resides at F000:0000H. After switching to your
; 80386/8086 Board (IN port EDH, Master Z80 monitor "W" or in this case "O" command), the Monitor should immediately come up.
;
; To burn two 28C256 EEPROM's with a Wellon VP290 Programmer...
; Load .BIN file. Select Even bytes (1st of 2) for one ROM and "From File HEX address" and "Buffer Address"
; leave 0000 in the dialog boxes, do not change "File Size (HEX) either".
; Repeat for ODD addresses. In each case the Edit Box code should appear from 0000H-7FFFH if the ROM is read back.
;
; Remember the Console OUT routines CAN be different, The "Normal" monitor and IDE diagnostic sections ALWAYS go through the
; Propeller driven (or any serial type) Console out routine (CO: etc.). This by default is also the case

```

```

PRINTER_STATUS EQU    5           ;IN, HP PARRELL PORT

;-----DISPLAY Words Memory -----
; This routine forces the CPU to do RAM word reads rather than a byte reads.
; It is used to test the hardware's ability to do 16 bit reads on odd and even addresses.
; This is very important. "Normal" byte reads will not show such a hardware problem.
; A block or RAM/ROM read with the "D" & "P" commands must be identical

DISPLAY_RAM_WORDS:

;*****
;
;   Bootstrap Handler      (IBM-PC Software Interrupt 19H)
;
;       SYSTEM - BOOTSTRAP LOADER
;
;   For a floppy the BIOS will try to read sector 1, head 0, track 0 from drive A:
;   to 0000h:7C00h.  If this fails we will just abort.
;
;   For the IDE/CF Cards the BIOS will try to read sector 1, head 0, track 0 from
;   drive #2 of the IDE Board to 0000h:7C00h.  If this fails we will just abort.

```

```

;
; For a hard disk, the BIOS will read sector 1, head 0, track 0 of the 2nd CF-Card
; on the Dual IDE board. This sector should contain a master bootstrap loader and
; a partition table (see http://www.ctyme.com/intr/rb-2270.htm#Table650).
;
; After loading the master boot sector at 0000h:7C00h,
; the master bootstrap loader is given control with:-
;
;         CS:IP = 0000h:7C00h.
;         DH = access bits 7-6,4-0: Don't care
;         bit 5:=0 device supported by INT 13.
;         DL = boot drive
;             00h first floppy
;             80h first hard disk
;
; True IBM PCs and most clones issue an INT 18 (cassette) if neither floppy nor hard
; disk have a valid boot sector. We will just abort.
;
; To accomplish a warm boot equivalent to Ctrl-Alt-Del, store 1234h in
; 0040h:0072h and jump to FFFF:0000h. For a cold boot equivalent to
; a reset, store 0000h at 0040h:0072h before jumping..
;
; BUG: If when loading the remainder of the DOS system files fails, various versions
; of IBMBIO.COM/IO.SYS incorrectly restore INT 1E before calling INT 19, assuming
; that the boot sector had stored the contents of INT 1E at DS:SI instead of on
; the stack as it actually does.
;

;*****
;
;   Keypressed Handler      (for IBM-PC is int #9 via 8259A to 24H in RAM)
;

```

```

;      IRQ1 - KEYBOARD DATA READY
;
;      This interrupt is generated when data is received from the keyboard. This is normally
;      a scan code (from either a keypress OR a key release), but may also be an ACK or NAK
;      of a command on AT-class keyboards. (Note My Propeller Board translates the scan codes ASCII chars)
;
;
;      Note: This IRQ may be masked by setting bit 1 on the 8259A I/O port 21h.
;
;
;      If the BIOS supports an enhanced (101/102-key)keyboard, it calls INT 15/AH=4Fh after reading the
;      scan code from the keyboard and before further processing all further processing uses the scan code
;      returned from INT 15/AH=4Fh. (This is not done here)
;
;
;      The default interrupt handler is at F000h:E987h in 100%-compatible BIOSes. The interrupt handler performs
;      the following actions for certain special keystrokes:-
;
;
;      Ctrl-Break clear keyboard buffer, place word 0000h in buffer, invokes INT 1B, and sets flag at 0040h:0071h
;      SysReq invokes INT 15/AH=85h (SysReq is often labeled SysRq)
;      Ctrl-Numlock place system in a tight wait loop until next INT 09
;      <<<<<< None of the above "extra" items are yet implemented >>>>>>
;
;
;      Shift-PrtSc invokes INT 05 (This is now implemented here).
;      Ctrl-Alt-Del jump to BIOS startup code (either F000h:FFF0h or the destination of the jump at that address)
;      Pause & Ctrl-Num_Lock will halt Console Output until the next keyboard input
;

;*****
;
;   Console Input Handler   (Software Interrupt 16H)
;   Return with keyboard buffer character in AL
;
;Input: AH = 00h           KEYBOARD - GET KEYSTROKE
;
;Return:AH = BIOS scan code
;       AL = ASCII character
;
;       Note:   On extended keyboards, this function discards any extended keystrokes,
;               returning only when a non-extended keystroke is available. The BIOS
;               scan code is usually, but not always, the same as the hardware scan
;               code processed by INT 09. It is the same for ASCII keystrokes and most
;               unshifted special keys (F-keys, arrow keys, etc.), but differs for shifted
;               special keys. Some (older) clone BIOSes do not discard extended keystrokes
;               and manage function AH=00h and AH=10h the same.
;
;Input: AH = 01h           KEYBOARD - CHECK FOR KEYSTROKE
;
;Return:ZF set if no keystroke available
;       ZF clear if keystroke available
;       AH = BIOS scan code
;       AL = ASCII character

```

```

;           Note: If a keystroke is present, it is not removed from the keyboard buffer;
;           however, any extended keystrokes which are not compatible with 83/84- key keyboards
;           are removed by IBM and most fully-compatible BIOSes in the process of checking
;           whether a non-extended keystroke is available. Some (older) clone BIOSes do not
;           discard extended keystrokes and manage function AH=00h and AH=10h the same.
;
;Input: AH = 02h      KEYBOARD - GET SHIFT FLAGS
;
;Return:AL = shift flags (see below)
;      AH destroyed by many BIOSes
;           Bitfields for keyboard shift flags:-
;           7      Insert active
;           6      CapsLock active
;           5      NumLock active
;           4      ScrollLock active
;           3      Alt key pressed (either Alt on 101/102-key keyboards)
;           2      Ctrl key pressed (either Ctrl on 101/102-key keyboards)
;           1      left shift key pressed
;           0      right shift key pressed
